SOURCE: AN UkrRSR. Dopovidi, no. 3, 1966, 302-306

TOPIC TAGS: second order differential equation, Volterra equation, matrix element, integral equation

ABSTRACT: There is a system of differential equations

$$x'' + \lambda^2 Q(t)x = F(t, x, x'), \lambda \neq 0,$$

where $Q(t)$ is a quasi-diagonal matrix of order $n \times n$ and λ is an arbitrary parameter. It is shown that when appropriate conditions are imposed on the matrix $Q(t)$, this system is reduced to a standard equivalent system of Volterra type integral equations. The result is realized by means of a matrix differential invariant especially constructed of matrix $Q(t)$ elements. Presented by I. Z. Shtoralo, member of AN URSR.

TITLE: On a variational problem on the dynamics of a body of variable mass

SOURCE: AN UkrRSR. Dopovidi, no. 9, 1966, 1125-1127

4/2 t²TOPIC TAGS: flight dynamics, variable mass ~~body~~, variational method, Cauchy problem,
flight mechanicsABSTRACT: The variational problem of the motion of a body of variable mass described
by the equation

$$m(t) \frac{dv}{dt} + A_0 v^2 + c \frac{dm}{dt} + m(t) g = 0. \quad (1)$$

where $m(t)$ is the variable mass of the body, v is its velocity, c is the relative constant exhaust velocity, and g and A_0 are the gravitational and drag constants, respectively, is analyzed. This variational problem is formulated as follows: from all possible functions $m(t)$, we are to choose that one which maximizes the performance functional

$$x(t) - x_0 = \int_{t_0}^{t_f} v(t) dt. \quad (2)$$

Card 1/2

L 47561-66

ACC NR: AP6032412

To solve this problem, the asymptotic methods of the theory of differential equations are applied. By various substitutions, equation (1) is reduced to the canonical form

$$z' + f(t)z = 0, \quad (3)$$

where $f(t) < 0$ for $t \geq t_0$ and $\int_{t_0}^{\infty} |f'(t)| dt < \infty$.

The solution of the Cauchy problem for equation (3) with the initial condition

$$v(t_0) = v_0 \quad (4)$$

is sought. The fundamental system of solutions of equation (5) is derived in asymptotic form, and finally, the approximate general solution $v(t, t_0)$ is presented in analytic form which at $t \rightarrow \infty$ becomes an expression that does not depend on the initial conditions. Therefore, the variational problem (2) is reduced to determining the maximum of a functional whose explicit form is known. The problem of determining the law of variation for $m(t)$ is considerably simplified because this law must be established in a certain class of functions with one unknown parameter. TITLE: Dynamic expansion of an elastic-plastic cylinder,
failure of the material being taken into account

PERIODICAL: Prykladna mekhanika, v. 8, no. 4, 1962, 419 - 424

TEXT: An infinitely long elastic-plastic cylinder is considered. At the initial moment of time, the internal surface of the cylinder is subjected to the pressure pulse I; no forces act on the surface in the following moments. At $t = t_0$, the plastic strains, which at first arise only at the interior surface, propagate through the entire cylinder; thereupon plastic expansion follows, accompanied by the appearance of radial cracks. A number of assumptions are made with regard to the material of the cylinder and the directions of the stress and strain-rate tensors. The system of equations, describing the processes under consideration, is set up. After the material has passed completely into the plastic state, the cylinder begins to expand,

Card 1/3

Dynamic expansion of an ...

S/198/62/008/004/005/006
D407/D301

its boundaries change , and radial cracks appear. Formulas and notations of an earlier work by the author are used. It is assumed that the radial cracks lead to failure of the material at the moment in which the internal radius of the cylinder assumes the value $a = a_s$, and the initial pressure I is so great that the cylinder continues to expand. The problem reduces to solving the differential equation

$$\frac{dx}{dz} + xf(z) + \frac{2K}{\rho} \varphi(z) = 0, \quad (19)$$

where $x(z) = (dR / dt)^2$ is the square of the relative rate of failure; R is the relative radius of failure; $z = R / a_0$; f and φ are certain functions; K is the plastic constant; ρ is the density. Eq. (19) is solved in quadratures. The formula for the pressure, which leads to complete failure of the elastic-plastic cylinder, shows that the case under consideration differs from the case of an ideally plastic cylinder by virtue of the initial conditions. There is 1 figure.

TITLE: Dynamic expansion of a plastic hollow sphere taking into account the breakdown of the material

PERIODICAL: Prykladna mekhanika, v. 7, no. 3, 1961, 413 - 420

TEXT: The author states that in an earlier paper (Ref. 2: Dynamichne rozshyrennya plastichnogo tsylindra z urakhuvannym ruynuvannya materialy (Dynamic Expansion of a Plastic Cylinder Taking into Account the Breakdown of the Material) Prykladna mekhanika, t. III, v. 4, 1957) he dealt with the case of the dynamic expansion of an axisymmetric body. He now extends his method to the case of spherical symmetry. A plastic hollow sphere, internal radius a_0 , external radius b_0 , is considered. At the initial instant of time there is an impulse of pressure on the internal surface of the cylinder, and at subsequent instants there are no forces acting on the surface. A

Card 1/5

Dynamic expansion of a ...

25114
S/198/61/007/003/009/013
D264/D303

spherical polar coordinate system is taken, with its origin at the center of the sphere. The deformations in the θ -direction and in the φ -direction will be equal. Under the impulse I the plastic sphere will expand in such a way that in material already deformed in the θ and φ directions at the instant $t = t_s$, radial cracks will be formed, whose expansion leads to the breakdown of the material. In an incompressible material, the cracks appear first on the inside surface. After the cracks appear, the material is divided into two regions by a sphere of radius $r = r_s$ into two zones - one plastic and one in a condition of breakdown. The velocity of fragments in the breakdown state is to be found from the velocity in the limiting plastic zone. In the limiting zone, the pressure acts in the radial direction, giving $\sigma_\theta = \sigma_\varphi$ for $r = r_s$. It is assumed that the material of the sphere is incompressible and satisfies in the breakdown state, the conditions of ideal plasticity, and that the directions of the principal axes of the stress tensor and the tensor of deformation velocity coincide for each point of the plastic

Card 2/5

Dynamic expansion of a ...

2511
S/198/61/007/003/009/013
D264/D303

zone. The following notation is adopted: v_r , v_θ , v_φ are the components of velocity of a fragment; σ_r , σ_θ , σ_φ , $\tau_{r\theta}$, $\tau_{\theta\varphi}$, $\tau_{\varphi r}$ are the components of the stress tensor; e_r , e_θ , e_φ , $\gamma_{r\theta}$, $\gamma_{\theta\varphi}$, $\gamma_{\varphi r}$ are components of the deformation velocity tensor; ρ is the density of the material, and K the plastic constant. Under the conditions of radial symmetry and with the above assumptions, the equation of motion, the conditions of incompressibility, and the condition of ideal plasticity are given. By a consideration of the boundary conditions a solution is obtained with the form

$$\left(\frac{da}{dt}\right)^* = \frac{b}{a^3(b-a)} \left[D - \frac{8K}{3\rho} (b^3 \ln b - a^3 \ln a) \right]; \quad (8)$$

where D is a constant of integration and $a(t)$, $b(t)$ are connected by the relationship $b^3 - a^3 = c_0^3$ ($c_0 = \text{const}$),

Card 3/5

Dynamic expansion of a ...

25114

S/198/61/007/003/009/013
D264/D303

and a and b are stated to be variable radii. (8) satisfies the problem up to the appearance of the crack. Integrating (1) and solving for boundary conditions, the author obtains Eq.

$$I_1^2 = \frac{8}{3} K_Q \frac{b_0 - a_0}{a_0 b_0} \left(a_0^3 \ln \frac{b_0}{a_0} - a_0^3 \ln \frac{b_0}{a_0} + c_0^3 \ln \frac{b_0}{b_0} \right). \quad (15)$$

It is supposed that the crack appears when the internal radius $a = a_s$. The instantaneous coordinates of a fragment of the material are given by $r = r_0 + u(r_0, t)$ where r_0 is the initial coordinate and u_0 the radial displacement. In the case of spherical symmetry the displacements in the θ and φ directions are given by $\epsilon_\theta = \epsilon_\varphi = \frac{u}{r}$ and in the boundary condition $(\frac{u}{r})_{r=r_s} = \epsilon_s$. For the plastic zone $r_s < r < b$, the same conditions hold as previously. Finally, the impulse necessary for complete breakdown is given by

Card 4/5

Dynamic expansion of a ...

25114
S/198/61/007/003/009/013
D264/D303

$$I_n^2 = \frac{8}{3} K_0 a_0^3 \frac{1}{P(z_0)} \left[G(\lambda_0, z_0) + \frac{\sqrt[3]{a^2 \gamma^4}}{L(\lambda_0, z_0)} \int_{z_0/a_0}^{b_0/a_0} \varphi(\xi) e^{\int_{\xi}^{b_0/a_0} f(\eta) d\eta} d\xi \right]. \quad (30)$$

where $z_0 = b_0/a_0$, and in this case the initial velocity of separation of the fragments is given by

$$V = \frac{a}{\sqrt[3]{(1+a)^2}} \sqrt{x(z_0)} = \sqrt[3]{a \gamma^2} \sqrt{x(z_0)}. \quad (34)$$

A numerical case is considered in which $a_0 = 1$ cm, $b_0 = 2$ cm, $\rho = (7.8/981)$ gr.sec²/cm⁴; $2K = 2000$ kg/cm²; $\epsilon = 0.05$. It is found that in this case breakdown begins under an impulse of $3425 \cdot 10^{-5}$ kg sec/cm² and external radius $b = 2.105$ cm. There are 3 figures and two Soviet-bloc references.

TITLE: Effect of boundary conditions on stress concentration at the hole in a spherical shell

SOURCE: Prikladnaya mekhanika, v. 1, no. 6, 1965, 42-47

TOPIC TAGS: stress concentration, spheric shell structure

ABSTRACT: The article considers the question of the effect of the outer edge of a finite spherical shell on the stress concentration at the circular hole at the center of the shell, which is subjected to uniform pressure. Use is made of the method of initial parameters, which makes it possible in simple form to determine the state of stress in a shell with a hole and to consider numerical examples. A concrete example is given.

AUTHOR: Pavlyuk, P.G., Assistent

TITLE: Investigating the accuracy of multi-tool turning

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy. Mashino-stroyeniye, no. 9, 1960, 122 - 135

TEXT: The system of machine-component-tool was investigated under a static load to simplify calculation of machining accuracy of multi-tool turning. The coefficients of rigidity of assemblies in a semi-automatic, type 116-2 at the Gor'kovskiy avtomobil'nyy zavod (Gor'kiy Car Plant) were measured, and then the radial displacements of the system were computed. The loading device was designed by the author. It is mounted on the front slide, with ring dynamometers pressing against a ball head on one side and a spherical washer on the other side (Fig. 1). The nut 13, is threaded on pin 14, and the load is thus transmitted to the machined component 15. and front slide 18. The displacements of component in sections 1-1. 2-2, 3-3 and 5-5 were measured by microindicators 9, 10, 11 and 12-13.

Card 1/64

Investigating the accuracy of ..

12, whereas shifts in the system machine-component-t-11 were indicated by dials 1, 2, 3 and 8 with the use of antenna s-1'. The loading device 12 is a thin tie-rod load inclined to the horizontal, the initial conditions were not set by the author. In section 16, the change of rigidity coefficient of the system in section 1-1 is due to increase of equivalent force. Other sections showed different results. An equation is given for displacement of the system in the horizontal plane due to action of m forces of the front slide. When the component is not rigid, then the displacements are determined by deformations due to bending of the component. Only rigid workpieces are considered in the article. In its bearing in the system where the displacement of the system has been considered, the displacements of machine-component-t-11 are related to the compliance of the system. The accuracy of the relative equation concerning the total displacements and which takes into account the coefficient of displacement is here given to 10%. The physical meaning of the above coefficients will be explained by the variation of rigidity of the semi-automatics with the use of load, as well as with changes in the method of applying load.

front slide. The cutting forces produce deformations, and these cause reciprocal disposition of cutting tools in relation to the datum surfaces of the machined component. The displacements of the system in multi-tool turning can be considered as a sum of compliances of this system, due to action of each tool. The compliance in the case of rigid component may be assessed experimentally during turning. Tests were carried out with three tools, either by conventional turning or step-turning. The ratio between the small and large allowance was fixed at 1:10. The results permit the surface plot of compliance for the system to be made. This can be traced for any length of the rigid component, when ordinates of the curve of effect on compliance for another workpiece with different length are known. Fig. 11 indicates the surface of compliance in the case of turning with tools having a 90° rake in plane Φ . The proposed method of computing deviations in machining as a function of the compliance is made with the following assumptions. The effect of several forces of cutting on the coefficient of rigidity of assemblies in a semi-automatic is calculated by introducing the coefficient of displacement, when compared to the action of a single force. The action of components of forces is considered by

D221/D304

ordinates of the curve due to effect of the compliance which is obtained when turning specimens. The tests established that the coefficient of displacement is equal for all tools, when the rigidity of a system has a positive value. The above ordinates of compliance are easily determined without special gadgets, and using reject specimens. The operation itself is simple. There are figures.

TITLE: The rigidity of the system during the multi-tool turning of rotary cam pivot journals

PERIODICAL: Referativnyy zhurnal, Mashinostroyeniye, no. 3, 1961, 36, abstract 3B320. (Nauchno-tekhn. inform. byul. Leningr. politekhn. in-t, no. 9, 1959, 15-24)

TEXT: The multi-tool 116-2 lathe was tested as to the rigidity of the system lathe - part - tool during the turning of rotary cam pivot journals with the aid of several tools. The dislocation of the system was determined by the difference in diameter turned by the measuring tool (at small cutting depths) prior to and during the action of another tool removing a big allowance. The mobile force applied to the system during the removal of a big allowance is expressed by the radial component of the cutting force. A graph is plotted expressing the regularity of dislocation changes of the system in a definite cross section as a function of the position of the mobile force maintaining a constant direction. With the aid of several graphs for different forces the combined

TITLE A Contribution to the Problem of Investigations of the Conditions for Chemical Decomposition of Solids with Formation of a Hydrate Precipitate (K voprosu ob issledovaniiakh osloveniia kremnicheskogo razlozheniya tverdykh veshchestv s obrazovaniem gidratnogo osadka)

PERIODICAL Sb. nauchn. tr. Mosk. in-t tsve'n. met. i zolotoi i VNIIO tsve'n. metallurgii, 1957, Nr 26, pp 200-211

ABSTRACT The employment of air-tight, heated steam mills to study the solution reaction of scheelite in HCl made it possible to eliminate the inhibiting effect of hydrate films and to attain an actual state of equilibrium with comparative speed. The significant value of the equilibrium constant $K = [CaCl_2] \cdot [HCl]^2$ appx 9.500 confirms that the high excess and high strength of HCl employed in industry is not justified by the equilibrium conditions and merely constitute a method of combatting inhibition of the reaction of the hydrate films that come into being. Employment of a steam charge in the acid treatment of scheelite provides a more

TITLE: Certain features of fabricating welded chemical equipment from titanium

SOURCE: AN UkrSSR, Institut elektrosvarki. Proektirovaniye svarynykh konstruktsii
(Design of welded structures), Kiev, Naukova dumka, 1965, 179-106

TOPIC TAGS: titanium, titanium alloy, welding technique, construction material,
chemical engineering/ VT 1 titanium alloy

ABSTRACT: Problems related to welded titanium in fabrication of chemical equipment are discussed. The titanium alloy VT-1 used in this work has specific gravity of 4.5 g/cm³, strength of 60 kg/mm², ductility of 20-25%, and good cutting, welding, and melting characteristics. Its disadvantages include a tendency to react with oxygen and nitrogen (above 600°C), a tendency to form fissures in the weld under high concentration of hydrogen or when the unannealed metal is subjected to plastic deformations, unsatisfactory performance under a friction load, and a significant change of its mechanical properties with an increase in temperature. The welding techniques involved in constructing pressure vessels, filters, and heat exchangers are discussed; the problem of the limited variety of titanium structural stocks is

Card 1/2

L 60134-65
ACCESSION NR: AT5017707

2

considered, and protection of titanium components from contamination by gases is explained. Fuller utilization of titanium in chemical equipment will depend on the findings of more detailed studies on the economics of titanium construction; the results of further technical studies on the heat treatment of titanium; the perfection of a method for welding titanium to low carbon and alloy steels; accumulating more exact information on titanium structural characteristics; the development of specific equipment that would call for less titanium and would make fuller use of its advantages. Such equipment may involve the use of titanium-lined materials.

ABSTRACT: A short review of different welding techniques applied to nonferrous metals and high-alloy steel is presented by the engineers of the plant "Progress" which specializes in the production of machinery and equipment for chemical plants. The methods used in this plant were grouped as follows: 1) manual arc welding with fusible or infusible electrodes under different protective gases;

Card 1/3

ACCESSION NR: AP4039581

2) automatic and semiautomatic welding with different flux types and filler metals. Infusible tungsten electrodes were used in the manual argon arc welding of high-alloy steel to thin sheets of titanium, nickel, and copper. The same technique was applied to the welding of steels OKh23N28M3D3T and St. 3 if metal thickness did not exceed 4 mm. The composition of filler metals was selected to be as close as was possible to that of the welded alloys, with the exception of nickel NP-2 (which showed best results with the use of NMts-2.5 wire), and of aluminum details. Welding of the latter required special devices such as the UDAR-300 machine. In manual arc welding, the electrodes "Progress-50" were used on nickel NP-2, and the electrodes "Komsomolets-100" on the welds of steel St. 3 to brass L62. The electrodes made of wire Sv-25Kh25N16G7 coated with the TsL-8 alloy were used in welding steels St. 3 to Kh23N18. Greater economy was achieved with the arc welding under carbon dioxide with fusible electrodes and with the Sv-05Kh19N9F3S2 wire used as a filler. These welds were made with the semiautomatic welders A-547 and A-537. The latter method was applied mainly to the chromium nickel steel 1Kh18N9T. Nickel alloy NP-2 was welded to different metals semiautomatically under the ceramic flux ZhN-1 or ZhN-2 with filler metals NP-2 and Sv 04Kh19N9. Machine parts made of titanium alloy VT-1 were welded semiautomatically under the flux AN-T1 or AN-T3 with a degassed filler (hydrogen content below 0.004%). The combinations of flux K-8 and filler Sv-04Kh19N9 or flux AN-26 and filler

Card 2/3

ACCESSION NR: AP4039581

Sv-05Kh19N9F3S2 were used in the joints of steel 1Kh18N9T or of a two-layer steel St. 3 + 1Kh18N9T. The best results were obtained in welding of acid-resistant metals with flux AN 26 and with Sv-07Kh25N13 filler. The men who developed these techniques for nickel and titanium welding at the plant "Progress" were rewarded with a VDNKh medal. Orig. art. has: 2 tables and 2 photographs.

TITLE: Electric arc welding of nickel.

PERIODICAL: Khimicheskoye mashinostroyeniye, no. 5, 1961, 40-42

TEXT: The welding department of the Zhdanovskiy metallurgicheskiy institut (Zhdanov Metallurgical Institute), in cooperation with the workers of the Zavod "Progress" ("Progress" Plant), has developed and introduced an automatic, semi-automatic and manual electric-arc welding method of НП-2 (NP-2) nickel permitting composite welds to be obtained. The production of the ~~ЖН-1~~ (ZhN-1) ceramic flux proposed by the institute and of the ~~Прогресс-50~~ (Progress-50) electrodes developed by the authors was started at the electrode shop of the "Progress" Plant. The article contains a detailed description of the above-mentioned methods used for welding the parts of a mixing device. The casing was made of NP-2 nickel 500 mm in diameter and 3,000 mm long with welded flanges and pipe junctions. The casing walls were 10 mm

Card 1/2

Electric arc ...

S/184/61/000/005/006/009
D041/D113

thick, and the pipe junctions 6 mm. The mixer consisted of a steel pipe with a 3 mm nickel coating. A **TC-17M**(TS-17M) automatic welding machine the ZhN-1 flux, and an **НП-2** (NP-2) electrode wire on the flux pair with direct current of additive polarity were used for welding. A **ПС-500** (PS-500) transformer served as feed source, and the flux granulation was 1.5-2.0 mm. The circumferential seams were welded using a **T-22** (T-22) welding manipulator and a **TC-17M**(TS-17M) tractor mounted on a special arrangement. The nickel pipe junctions were welded to the casing by a **ПШ-5** (PSh-5) semi-automatic machine using NP-2 wire 2.5 mm in diameter. In this case, the flux granulation was 0.8-1.3 mm. The welds were examined and tested under a hydraulic pressure of 2 gage atmospheres. They were tight, with neither cracks nor gas or slag inclusions. Corrosion tests in a caustic soda solution were carried out at 50°C for 50 hours. Good results were obtained. It is concluded that the use of the above-mentioned methods for manufacturing nickel devices permitted high-quality weld joints to be obtained. There are 1 figure and 3 tables.

TITLE: New Electrodes for Manual Arc Welding of Nickel

PERIODICAL: Sverchnoye priznacheniye, 1961, No. 4, pp. 22 - 23

TEXT: Conventional H-10 (N-10) and H-37 (N-37) electrodes for manual welding of nickel do not assure sufficiently high and stable strength of weld joints. Therefore the authors attempted to develop efficient and cheap electrodes with satisfactory technological properties, providing high quality weld joints. The thermodynamical regularities of metallurgical processes in the welding of nickel and a great number of experimental data were used as basis for investigations carried out at the welding department of the Zhdanov Metallurgical Institute and the Berdichev "Progress" plant. As a result, the new "Progress" electrodes were developed with acid type coatings containing titanium dioxide, fluorine concentrate, sodium fluoride, manganese, titanium powder, aluminum powder, kentonite and sodium silicate. The composition of the electrode coating is available at request. The electrodes are intended for manual electric arc welding.

Card 1/2

S/135/E1/000/104/008/012
A006/A101

welding of N-1 nickel by GOST 849-56 and of NP-1, and NP-2 nickel by GOST 442-2. The electrodes can be manufactured by pressing or dipping. The thickness of the coating is for 3, 4 and 5 mm diameter electrodes 1 - 1.2, 1.2 - 1.3 and 1.3 - 1.5 mm respectively. The electrodes permit welding in any position with d.c. of reverse polarity. Recommendations are given as to welding condition and, preparation of edges for welding. The electrodes assure easy excitation and stable burning of the arc, satisfactory formation of the weld joint, having no pores, cracks and gaseous or slag inclusions, and showing corrosion resistance equal to that of the base metal. The electrodes are recommended for the manufacture of important nickel structures. There are 4 tables and 3 figures.

fiz.-tekhn. n. 1957. Nr 2, pp 47-57 (In Pelorussian, summary
in Russian)

ABSTRACT Experimental data derived in induction annealing of worked
metals Armco iron and 1Kh18N9T steel are presented. The
nature of the structure (hardened, not fully recrystallized, or
fully recrystallized) is determined in accordance with the basic
parameters of induction heating (temperature and rate of heat-
ing) and the degree of deformation, the temperature zones for
incompletely recrystallized structures are plotted. Data on the
grain size of the metals investigated are presented relative to
temperature, rate of heating, and degree of deformation. Bib-
liography 9 references. 1. Metals--Induction heating

TITLE: Recrystallization Diagrams for Induction Heating

PERIODICAL: Although methods of annealing by induction heating have not been widely studied, research on the subject indicates their effectiveness in treating deformed metals and alloys, showing such advantages as (1) a fine and homogeneous structure, (2) speed, and (3) possibility of automation. In comparing the above method with regular furnace heating, the authors consider heating speed and not the holding period to be the decisive factor. Recrystallization of the following deformed specimens was studied: (a) commercial iron, heated in high frequency furnace MGZ-1C2 to 600, 700, 800, 900, 1,000 and 1,100° C at mean heating speeds of 1.1, 1.1, 1.3 and 1.3° C sec; (b) 1Kh18N9T-steel (C, 0.1%; Si, 1.3; Mn, 2.0; Cr, 17.0 to 20.0; Ni, 8.0 to 11.0;

Si, 1.5%; P, 0.05%; Ti, 0.05%) heated to 900° C., 950° C., 1000° C., and 1050° C. at 1° C./sec; and (c) 15% deformed heated to 300, 400, 500, 600, 700, 800, 900 and 1000° C. at 10° C./sec, 300 and 400° C./sec. Heated specimens were automatically immersed in water in order to fix the structure. (1) Influence of prior deformation on grain size: (a) Commercial iron with a deformation range of 5-75% has a 1.5 to 2 times finer grain (see Fig. 1) at recrystallization temperature. (b) 1Kh18N9T-steel with a deformation ranging between 11 and 75% has a slightly refined grain (see Fig. 2). Deformations from 30-75% hardly affect the grain size. (c) Copper also has refined grains at increased rates of deformation (see Fig. 3). Deviations from the mean grain size with deformation ranging from 10 to 75% amount to a maximum of 1 μm at 900° C and to 4 μm at 1000° C. (2) Effect of heating temperatures: (a) in commercial iron at 75% and 15% deformation (at 900° C) the mean grain size amounts to 31 and 37 μm, respectively. (b) in 1Kh18N9T-steel temperature
